

SOURCE DETECTION APPARATUS AND
METHOD FOR AUDIENCE MEASUREMENT

Field of the Invention

5 The invention relates to the field of television audience research, and more particularly, to the detection of the viewing of television signals originating from a signal source within a statistically sampled household.

Description of Prior Art

.0 As disclosed by Thomas et al., in U.S. Patent No. 5,481,294, which is assigned to the same assignee as the present invention and the disclosure of which is herein incorporated by reference, the signal (i.e., television or radio), that has been selected, and is being viewed or heard, by an audience member on a television or radio receiver in a statistically selected household, may be determined by ascertaining the channel to which the tuner of the television or radio is tuned. This channel information is stored locally for subsequent retrieval by a central data collection office. The central data collection office matches the retrieved channel information against a cable/station record which indicates which station corresponds to which channel and/or against a program record list of

5

0

5 television or radio programs which were transmitted on that
channel in order to determine the television or radio pro-
gram that the audience member selected. As noted in U.S.
Patent No. 5,481,294 by Thomas et al., this process becomes
cumbersome as the number of signal sources, the number of
channels, the changes to channel mappings at a cable head-
end, and/or the number of television or radio programs in-
crease, and can fail to produce usable data if there is an
error in the program record list that provides the concor-
dance between channels and programs.
0

Several approaches have been proposed that are
intended to avoid the cumbersome cable/station record and/or
program record list manner of keeping track of which station
and/or which programming is available from which signal
source and channel within a sampled household. As an exam-
ple, one such approach has employed a program monitoring
system that reads an identifying code embedded in the pro-
gram, and uses the ancillary code to identify the program to
which the television or radio was tuned.
5

0 As another example, a program signature is ex-
tracted from the program signal selected for use (i.e., for
viewing if the signal is a television signal, or for listen-

ing if the signal is a radio signal) in the sampled household and is later compared to previously extracted reference signatures in an effort to match the program signature to a previously extracted reference signature in order to thereby
5 identify the selected program. Accordingly, this signature approach is a correlation system which uses a sample frequency that is less than the frequency of the program signal.

Such monitoring equipment in the sampled household
10 also stores a time stamp in addition to the ancillary code or program signature. The time stamp is used to determine the time and date of viewing and/or listening relative to the selected program.

Thomas et al., in U.S. Patent No. 5,425,100, and
15 U.S. Patent No. 5,526,427, both of which are assigned to the same assignee as the present invention, teach a hierarchical, multi-level encoding system for identifying a transmitted program by reading an ancillary program identifying code which is sequentially added to the program as it passes
20 through various stages of a program distribution network. The disclosures of U.S. Patent No. 5,425,100 and U.S. Patent No. 5,526,427 are hereby incorporated by reference. Other

program monitoring systems employing ancillary codes which are embedded in a transmitted program are taught by Haselwood et al. in U.S. Patent No. 4,025,851, and by Crosby in U.S. Patent No. 3,845,391.

5 A program monitoring system that exclusively relies on ancillary codes may produce inaccurate results when ancillary codes are either intentionally or accidentally omitted from program signals. Even when the original program signal is encoded with an ancillary code, there is a
10 risk that the ancillary code will be intentionally removed before the program signal is viewed or heard. There is also the risk that ancillary codes may be accidentally removed before the program in which they are embedded is viewed or heard. For example, ancillary codes that are embedded in
15 video or audio program signals so that they are undetectable to a viewer or listener, or so that they are at least unobtrusive enough to be no more than minimally detectable by a viewer or listener, are commonly stripped from the video or audio program signals when the video or audio program signals are compressed (e.g., such as by the MPEG II compression scheme used with digital television signals).

Moreover, ancillary codes, which are inserted into vertical blanking intervals (VBI) of the video portions of program signals, and which survive passage through the signal transmission chain so as to be received by a user's television receiver, are commonly removed from the video before the video is applied to the CRT of a television. As a result, non-intrusive acquisition of these VBI ancillary codes is impractical because such non-intrusive acquisition usually requires the use of probes which generally pick up the video sent by the tuner to the CRT after the VBI ancillary codes have already been stripped from the video.

Therefore, ancillary codes in the vertical blanking interval are more easily detected if the monitored television receiver is opened so that leads of the monitoring equipment can be soldered to video test points of the television receiver at which the ancillary codes are still present. However, such an arrangement is intrusive, leading to objections by the members of the statistically sampled households.

Signal comparison program monitoring systems, other than signature matching systems such as those described above, have also been used in order to determine the

signal sources (e.g., channels) of the programs being viewed or heard. One of the oldest known signal comparison program monitoring systems compares a synchronization component of a television program signal selected by a television tuner with a corresponding synchronization component in a program signal selected by a reference tuner. This signal comparison program monitoring system credits viewing to the signal source selected by the reference tuner when and if the two synchronization components match within some predetermined error.

Currey, in U.S. Patent No. 3,372,233, provided an early teaching of such a program monitoring system which compared the phasing of vertical synchronization signals for this purpose. Currey's approach was not particularly successful because there are times when the vertical synchronization components from different signal sources occasionally match. When this type of matching occurs, the program source measurement is ambiguous. Solar, in U.S. Patent No. 4,764,808, and Gall, in U.S. Patent No. 4,847,685, provided improved synchronization component measurement systems that did not entirely overcome the basic shortcoming of the Currey approach. In U.S. Patent No. 5,294,977, Fisher et

al. disclosed a synchronization component based measurement system operating in a restricted environment in which such phase coincidences can be avoided.

Another signal comparison program monitoring
5 system correlates a receiver signal, which may be extracted from a receiver being monitored, with a reference signal, which may be supplied by a reference tuner that is tuned consecutively to the possible program signal sources to which the monitored receiver may be tuned. This correlation
10 system determines the channel being viewed or heard when the correlation between the receiver signal from the monitored receiver and the reference signal from the reference tuner exceeds some predetermined value. This monitoring approach was initially adapted for the purpose of in-home identifica-
15 tion of viewed television programs by Kiewit et al. in U.S. Patent No. 4,697,209, the disclosure of which is herein incorporated by reference. The teachings of Kiewit et al. have been expanded upon by Thomas et al., in U.S. Patent No. 5,481,294, who described the use of signatures extracted
20 from either a video component or an audio component of a receiver signal, and who discussed the operational advantages of using non-invasive sensors to acquire the components.

5 A further comparison program monitoring system was
placed in commercial service in 1984 by the A. C. Nielsen
Company and was internally referred to as the Real Time
Correlation (RTC) system. The RTC system used a combination
of (i) vertical synchronization component matching and (ii)
audio correlation in order to identify an unknown signal.
The RTC system did so by first making a preliminary identi-
fication based upon matching of vertical synchronization
components. However, this preliminary identification would
10 not be unique if the unknown transmitted signal, for exam-
ple, was one of several sync-locked signals originating at a
local cable head-end. Therefore, the RTC system resolved
ambiguities by correlating the audio component of the se-
lected transmitted signal from the monitored television with
15 the audio component of the reference signal from the refer-
ence tuner whose synchronization component matched the
synchronization component of the transmitted signal.

20 Correlation program monitoring systems are gener-
ally more robust and less affected by signal degradation
than are code reading program monitoring systems. Even so,
a signal correlation program monitoring system, which com-
pares two signals (e.g., a receiver signal selected by a

monitored television at a television viewing site in a statistically sampled household, and a reference signal selected by a reference tuner at a different local reference site), works best when the two signals to be correlated are both high quality replicas of what was actually transmitted. If one of the correlated signals, such as the receiver signal selected by the monitored television, is acquired by a non-intrusive sensor at the television viewing site, and if the other correlated signal, such as the reference signal selected by the reference tuner, is acquired from the audio or video circuitry of a tuner at a different local reference site, artifacts introduced by the non-intrusive measurement at the television viewing site may have a substantial adverse impact on the correlation between the receiver and reference signals. To reduce such artifacts, Thomas et al., in the aforementioned U.S. Patent No. 5,481,294, teach the suppression or removal of background noise from an audio signal acquired by a non-intrusive microphone at the receiver viewing or listening site.

Another problem facing signal correlation systems is that, because signal correlation systems require an ongoing collection of reference signatures by equipment dedi-

5 cated to monitoring the signals transmitted from each program signal source in whatever regional market is being measured, the operating cost of a signature-based program monitoring system is generally higher than that of a comparable program monitoring system relying on ancillary codes.

10 A problem facing all, or nearly all, program monitoring systems arises from signal sources which originate within the household itself. Signal sources of this sort may include computers or video games, which use the monitored television's display, and video cassette (or tape) recorders, which play program signals that were recorded at earlier times or that are recorded on rental cassettes (or tapes). The use of such local signal sources is, with one exception to be discussed below, systematically excluded
15 from a long-established audience measurement parameter called "Households Using Television" (HUT) because the use of a television receiver with a locally generated signal does not fall within the scope of conventional television audience measurements.

0 Moreover, if a local signal source is not identified as such, a program monitoring system could either (i) erroneously count viewing or listening based on this local

signal source as it would count viewing or listening based upon a remote signal source, or (ii) label the viewing or listening based on the local signal source as an unidentified activity. Either way, viewing or listening based upon a local signal source would be included as contributions to the overall HUT value reported by the program monitoring system in such a way as to create ambiguities.

The exception mentioned above relates to recording of programs by VCRs for later time shifted viewing. The reportable HUT value generally counts time-shifting viewing either at the time of recording or at the time of playback, but does not count at both recording and playback. By not counting at both recording and playback, double counting is avoided. Also, whether counting is done at the time of recording or at the time of playback, program monitoring systems strive to count only transmitted programs and seek to avoid counting non-transmitted programs, such as rented movies.

Also, a VCR typically has a number of modes in a non-record mode. For example, in a monitor mode, the VCR is used to pass through a currently selected transmitted program signal so that the signal may be viewed on a televi-

sion, but the VCR does not concurrently record the signal. In a tune/record mode, the VCR is used to pass through a currently selected transmitted program signal for both viewing and recording. In a non-tune/record mode, the VCR is used to record a program without concurrent viewing of the program on a television; thus, the program is recorded for time-shifted playing. In a play mode, the VCR is used to play transmitted materials, and as tune-shifted recordings, and non-transmitted materials, such as rented movies. In an off mode, the VCR is off. Because of this number of modes, a VCR presents one of the most difficult program monitoring challenges.

Early measurements of VCRs in sampled households involved monitoring of both the control switches and the tuners of VCRs. This monitoring resulted in the measurement of recording, which was credited to program ratings when recorded, and in the identification of all other uses as not contributing to program ratings. Thus, for example, when recording was counted as HUT viewing, all play activity was counted as non-HUT usage). These early measurements of VCRs involved a complicated and expensive disassembly and modifi-

cation of consumers' equipment in order to physically connect switch monitoring equipment to the VCR switches.

Subsequent improvements in VCR measurement provided less invasive, and in some cases entirely non-invasive, ways of acquiring the requisite signals. In U.S. Patent No. 4,633,302, Damoci teaches a method of picking up an artifact from the output of a VCR's erase-head in order to ascertain that the measured VCR is recording a tuned signal. Vitt et al., in U.S. Patent No. 5,165,069, teach a further improved measurement method in which all the status information (including a sensed erase-head output, which is commonly selected by different manufacturers to be a continuous wave (CW) tone lying between thirty and seventy-five KHz) is acquired from a sensor or pickup located immediately adjacent to, but externally of, the VCR's housing. The disclosure of Vitt et al. is herein incorporated by reference. Mostafa et al., in U.S. Patent No. 5,495,282, teach yet another non-invasive arrangement for monitoring the operation of a VCR by injecting encoded identification signals into the VCR and searching for that signal in the RF output from the VCR. Yet the monitoring of VCRs continue to be a difficult problem.

The present invention solves one or more of the above-noted problems.

Summary of the Invention

5 In accordance with one aspect of the present invention, a system for identifying a signal source supplying a program signal to a monitored receiver comprises program signature extracting means and signal source identifying means. The monitored receiver is located in a household. The program signature extracting means extracts a
10 reference program signature representative of an output of the monitored receiver and extracts a source program signature representative of the program signal supplied by the signal source. The program signature extracting means is located in the household. The signal source identifying
15 means identifies the signal source as a source of the program signal in response to the reference program signature and the source program signature.

In accordance with another aspect of the present invention, a system for identifying which of first and
20 second signal sources is supplying a program signal to a monitored receiver comprises program signature extracting

means and signal source identifying means. The first and second signal sources and the monitored receiver are located in a household. The program signature extracting means extracts a reference program signature representative of an output of the monitored receiver and extracts first and second source program signatures representative of an output of the first and second signal sources. The program signature extracting means is located in the household. The signal source identifying means identifies which of the first and second signal sources is a source of the program signal in response to the reference program signature and the first and second source program signatures.

In accordance with yet another aspect of the present invention, a system for identifying a program tuned by a monitored receiver comprises tuning means, program signature extracting means, signature correlating means, and code reading means. The monitored receiver is located in a household. The tuning means is separate from a tuner of the monitored receiver and tunes to programs tunable by the monitored receiver. The tuning means is located in a household. The program signature extracting means is operably coupled to the monitored receiver and to the tuning means,

and extracts a first program signature from an output of the monitored receiver and a second program signature from an output of the tuning means. The signature correlating means correlates the first and second program signatures. The
5 code reading means is operably coupled to the tuning means and reads an ancillary code from the output of the tuning means if the signature correlating means detects a match between the first and second program signatures.

In accordance with still another aspect of the
10 present invention, a system for determining an operating mode of a recording/playing device comprises tuning means, first, second, third, and fourth signal acquiring means, and determining means. The recording/playing device generates a recording indicating signal during recording and operates in
5 conjunction with a receiver. The tuning means is separate from a tuner of the receiver and tunes to a program signal. The first signal acquiring means acquires a first signal from an output of the recording/playing device. The second
10 signal acquiring means acquires a second signal from an output of the tuning means. The third signal acquiring means acquires a third signal from an output of the receiver. The fourth signal acquiring means acquires the record-

ing indicating signal. The determining means is coupled to the first, second, third, and fourth signal acquiring means and determines an operating mode of the recording/playing device dependent upon the first, second, and third signals and the recording indicating signal.

In accordance with a further aspect of the present invention, a system for measuring the use of a video recorder operably connected to a television receiver comprises source tuning means, television receiver signal acquiring means, and first and second comparing means. The television receiver receives a plurality of transmitted television signals. The source tuning means tunes to a source program signal corresponding to a transmitted television signal. The television receiver signal acquiring means acquires a signal displayed on the television receiver. The first comparing means compares a signal from the video recorder to the source program signal. The second comparing means compares the signal from the video recorder to the signal acquired by the television receiver signal acquiring means.

In accordance with yet a further aspect of the present invention, a method of determining the source of a signal selected for use by a user at a monitored receiver in

a household comprises the steps of: (a) selecting, by means of a source receiver, a source signal corresponding to a channel; (b) acquiring, by use of a non-intrusive sensor disposed proximate to the monitored receiver, a representation of the signal selected by the user; (c) comparing the representation of the signal selected by the user to the source signal in order to determine a difference between the representation and the source signal; (d) if the difference is less than a predetermined amount, identifying the representation as the source signal; (e) if the difference is not less than a predetermined amount, controlling the source receiver to receive a source signal corresponding to another channel and repeating steps (c) and (d).

In accordance with a still further aspect of the present invention, a method of reading an ancillary code operably associated with a user selected program signal transmitted from one of a plurality of program channels to which a household receiver in a household is tuned comprises the steps of: (a) acquiring the user selected program signal from the household receiver; (b) acquiring a source program signal from a predetermined one of the plurality of program channels; (c) comparing the source program signal

to the user selected program signal and, if the source program signal and the user selected program signal differ by less than a predetermined amount, reading the ancillary code from the source program signal.

5 In accordance with another aspect of the present invention, a method of identifying which of first and second signal sources is supplying a program signal to a monitored receiver, wherein the first and second signal sources and the monitored receiver are located in a household, comprises
.0 to following steps: (a) comparing a sync signal from an output of one of the first and second signal sources to a sync signal from an output of the monitored receiver; (b) if the sync signal from an output of one of the first and second signal sources matches the sync signal from an output
.5 of the monitored receiver, extracting a reference program signature representative of the output of the monitored receiver and a signature representative of the output of the one of the first and second signal sources; (c) identifying which of the first and second signal sources is a source
:0 of the program signal if the reference program signature and the signature representative of the output of the one of the first and second signal sources match; and (d) if the sync

5 signal from an output of the one of the first and second
signal sources does not match the sync signal from an output
of the monitored receiver, comparing a sync signal from an
output of another of the first and second signal sources to
a sync signal from an output of the monitored receiver and
repeating steps (b) and (c) as necessary.

Brief Description of the Drawing

10 Figure 1 is a schematic illustration showing the
components of a prior art television audience measurement
system which is improved by the present invention;

Figure 2 illustrates in greater detail the statis-
tically selected household of Figure 1 as measured in accor-
dance with the prior art;

15 Figure 3 is a schematic block diagram of a pre-
ferred embodiment of the present invention; and,

Figure 4 is a state table summarizing VCR measure-
ments which may be made using the apparatus of Figure 3.

Detailed Description of the Preferred Embodiment

5 A television audience measurement system 10 of the
sort taught by Thomas et al. in U.S. Patent No. 5,481,294 is
depicted schematically in Figure 1. Programs transmitted
from a plurality of program transmitters 12 (which are
10 depicted in the drawing as over-the-air transmitters, but
which may include any transmitter of program signals such as
CATV, direct satellite broadcast, and/or the like) are
received at a statistically selected household 14. The same
program signals from the same program transmitters 12 are
also received by a local monitoring site 16. Generally,
although not necessarily, the local monitoring site 16 of
the television audience measurement system 10 is located in
a corresponding regional market being measured, and serves a
15 plurality of statistically selected households, such as the
statistically selected household 14, which are located
within that regional market. All such statistically se-
lected households communicate their data to a central site
18.

0 Also, there may be a plurality of regional markets
each having a corresponding local monitoring site 16 and
each local monitoring site 16 serving a plurality of corre-

sponding statistically selected households 14. All such statistically selected households and all such local monitoring sites communicate their data to the central site 18.

5 Data, which may comprise identifying ancillary codes transmitted with the programs transmitted by the program transmitters 12, or which may comprise program signatures characteristic of such programs, are extracted from the received transmitted programs by both the statistically selected household 14 and the local monitoring site
.0 16, and the extracted data are sent from both the statistically selected household 14 and the local monitoring site 16 to the central site 18. The central site 18 compiles television audience reports based upon this data from the statistically selected household 14 and the local monitoring
5 site 16 as well as from all other statistically selected households located within the receiving area of the local monitoring site 16, from all other statistically selected households located within the receiving areas of all other corresponding local monitoring sites, and from all other
0 local monitoring sites.

In general accordance with the teachings of Thomas et al. in U.S. Patent No. 5,481,294, the portion of the

television audience measurement system 10 located within the statistically selected household 14 is shown in more detail in Figure 2. As shown therein, the program transmitters 12 transmit RF program signals to a signal input 20, which is generally shown as an antenna but which may be any other type of program signal input, such as a cable input, a satellite dish, and/or the like. The program signals received by the signal input 20 may comprise a plurality of channels of television programming and are routed to one or more television receivers 22, 22' of the statistically selected household 14.

Each of the television receivers 22, 22' may have associated with it a corresponding local (i.e., non-transmitted) video signal source 24, 24'. For example, the local video signal source 24 associated with the television receiver 22 may be a video game 26, and the local video signal source 24' associated with the television receiver 22' may be a VCR 28. The local video signal sources 24, 24' may be configured to send their output video signals to their corresponding television receivers 22, 22'.

Non-invasive signal sensors 30, such as microphones, photodetectors, inductive pickups, and/or the like,

are arranged, and are located, to acquire representations of the program signals selected for viewing on the television receiver 22. These representations are preprocessed by a preprocessing circuit 32 in a manner, for example, described
5 in the aforementioned U.S. Patent No. 5,481,294. The preprocessed representations are passed to a code reader 34 and to a signature extractor 36. The code reader 34 and the signature extractor 36 produce program identifying data from the preprocessed representations. Thus, for example, the
10 code reader 34 reads ancillary codes from the preprocessed representations, and the signature extractor 36 extracts signatures from the preprocessed representations.

The program identifying data extracted by the code reader 34 and the signature extractor 36 are sent to a data
15 storage and telecommunication processor 38 for subsequent transmission by way of a transmission medium 40 to the central site 18. Also, as is well known in the art, a local clock 42 associated with the data storage and telecommunication processor 38 is conventionally synchronized with a
20 master clock at the central site 18 whenever data are transferred between the statistically selected household 14 and the central site 18 over the transmission medium 40. The

transmission medium 40, for example, may be the public switched telephone network.

Similarly, non-invasive signal sensors 30' are arranged, and are located, to acquire representations of the program signals selected for viewing on the television receiver 22'. These representations are preprocessed by a preprocessing circuit 32'. The preprocessed representations are passed to a code reader 34' and to a signature extractor 36'. The code reader 34' and the signature extractor 36' produce program identifying data from the preprocessed representations. Thus, for example, the code reader 34' reads ancillary codes from the preprocessed representations, and the signature extractor 36' extracts signatures from the preprocessed representations. The program identifying data read by the code reader 34' and extracted by the signature extractor 36' are sent to the data storage and telecommunication processor 38 for subsequent transmission to the central site 18.

A people meter 43 may also be associated with the television receiver 22. The people meter 43 may be any of the people meters used by Nielsen Media Research, Inc. to meter the viewing habits of panelists, and generally deter-

mines the channel being viewed and the identities of the viewers of the television receiver 22. Also, a people meter 43' may be associated with the television receiver 22'. The people meter 43' may be similar to the people meter 43.

5 Figure 3 illustrates a program signal source detector 44 which may be used for the portion of the television audience measurement system 10 located within the statistically selected household 14 as shown in Figure 2 and which is suitable for accurately determining a local source
10 of signals, such as the VCR 28, being displayed on a monitored television, such as the television receiver 22'. If desired, the local metering site 16 may be eliminated. However, the local metering site 16 may be desirable in those markets where no one statistically selected household
15 receives all of the possible signals that are available in the market in which the statistically selected household 14.

As shown in Figure 3, a signal input 46, which is generally shown as an antenna but which may be any program signal input, such as a cable input, a satellite dish,
20 and/or the like, receives the program signals transmitted by the program transmitters 12. The program signals received by the signal input 46 may comprise a plurality of channels

of television programming. The program signals received by the signal input 46 may be split by a splitter 48 so as to be fed to both household entertainment equipment 50 and a channel selection apparatus 52. It should be noted here that, in determining the local source of video and/or audio being displayed by the television receiver 22', the output of the television receiver 22' is the reference signal, and the output of the channel selection apparatus 52, the game 26, the VCR 28, etc. is the source signal. The household entertainment equipment 50 and the channel selection apparatus 52 are located within the statistically selected household 14. As is known, a user of the household entertainment equipment 50 may choose from among many various interconnections in order to route a selected signal to a television and/or other equipment. In the interest of clarity of presentation, however, these various interconnections, which may be made by the user, are not shown in Figure 3.

In some cases, the selected signal is routed through the VCR 28 and then supplied to its associated television receiver 22'. This routing is commonly done at RF via a suitable cable from an RF output of the VCR 28 to an RF input of the television receiver 22', but the signal

may also be supplied to the television receiver 22' as a baseband audio signal from a VCR baseband audio output of the VCR 28 and/or as a baseband video signal from a VCR baseband video output of the VCR 28. For purposes of the program signal source detector 44, however, a VCR audio output 56 of the VCR 28 may be a baseband audio output of the VCR 28, and a VCR video output 58 of the VCR 28 may be a baseband video output of the VCR 28.

In one mode of operation of the VCR 28, hereinafter called the "TV mode," the RF signals from the signal input 46 are supplied directly to the television receiver 22', and the VCR 28 is not involved in the tuning process. The VCR 28 is in this mode whenever it is unpowered. In another mode, hereinafter called "VCR TUNE," a tuner within the VCR 28 is used to select one of the plurality of program signals received by the signal input 46 and to supply that selected signal as an output of the VCR 28 to its television receiver 22'. In a further mode, hereinafter called "PLAY," a signal stored on a video cassette (or tape) is supplied by the VCR 28 to its television receiver 22'. In yet a further mode, hereinafter called "RECORD," a program signal is recorded by the VCR 28 for later, time shifted viewing.

When the VCR 28 is in the RECORD mode, its erase head is powered so as to erase whatever old signal may be on the cassette (or tape) before the new signal is recorded. The operation of the erase head can be detected by finding some artifact of the erase head tone. As noted by Vitt et al. in U.S. Patent No. 5,165,069, this detection may be done in a non-invasive manner with an inductive sensor installed adjacent to the VCR 28. It also has been also found that an artifact of the erase head signal can often be detected directly from the VCR audio output 56 of some models of the VCR 28. The manner of detecting the erase head signal depends on the specific model of the VCR 28 being monitored. If an artifact of the erase head signal cannot be detected directly from the VCR audio output 56 of the VCR 28, the program signal source detector 44 may employ an input from a radiated signal pickup (not shown) of the sort disclosed by Vitt et al.

As shown in Figure 3, three of the non-invasive signal sensors 30' are employed to acquire representations of various signal components from the television receiver 22' whenever it is turned on. These three non-invasive signal sensors may include (i) a suitable sync signal pickup

60 which may be of the type disclosed in copending applica-
tion Serial No. 08/654,309 filed on May 28, 1996, which is
disposed adjacent the television receiver 22', and which
picks up a representation of the vertical and horizontal
5 synchronization pulses of the television receiver 22', (ii)
a video signal pickup 62 which may be of the type disclosed
in the aforementioned copending application Serial No.
08/654,309 filed on May 28, 1996 and which is arranged to
pick up a representation of the video signal being displayed
10 by the television receiver 22', and (iii) an audio signal
pickup 64, which may be a microphone as taught by Thomas et
al. in U.S. Patent No. 5,481,294 and which is used to ac-
quire the audio portion of the displayed program signal for
subsequent matching operations.

5 It is noted that the video signal pickup 62 may
not, and probably does not, acquire the full video signal
(some attenuation at the higher frequencies and the lowest
frequencies is common), but the failure of the video signal
pickup 62 to acquire the full video signal is of no partic-
0 ular concern in the overall measurement system of the pres-
ent invention because the matching operations disclosed
hereinafter can be conducted using only mid-frequency compo-

nents of the various video signals. It is also noted that the video signal pickup 62 may not, and probably does not, acquire the information contained in the vertical blanking interval of the video signal because the video signal pickup 62 is preferably located near the CRT of the television receiver 22' and because the vertical blanking interval is commonly not supplied to the CRT video of the television receiver 22'. Accordingly, ancillary codes located in the vertical blanking interval cannot be read from the output of the video signal pickup 62. It will be understood to those skilled in the art that both the video signal pickup 62 and the audio signal pickup 64 may employ appropriate circuitry (not separately shown) to match their output levels to the industry standard output levels of the signals obtained from the VCR video output 58 and the VCR audio output 56 against which they are matched.

If the television receiver 22' is a television model provided with an external video jack, such an external video jack can be used in lieu of the video signal pickup 62 and the sync signal pickup 60. Similarly, if the television receiver 22' is a television model provided with an external

audio jack, such an external audio jack can be used in lieu of the audio signal pickup 64.

5 The channel selection apparatus 52 of the program
signal source detector 44 employs a source scanning tuner
66. The source scanning tuner 66 has access to the signal
input 46 by means of the splitter 48 and may scan all of the
available programming channels under control of a controller
68. The controller 68 may be a PIC 16c65 that is slaved to
10 a digital signal processor 70 (which may be a Texas Instru-
ment model TMS 320C32-60) of a digital signal processing
module 71. The digital signal processor 70 may be consid-
ered to have a signature extraction portion 70' and a signa-
ture correlating portion 70''. The source scanning tuner 66
provides a video output 72 and one or two audio outputs 74
15 and 95 (the second of these being associated with a Second-
ary Audio Program (SAP) signal component of some television
transmissions) that are subsequently used in matching opera-
tions in order to determine the source of the signals dis-
played on the television receiver 22'.

20 As depicted in Figure 3, the program signal source
detector 44 is capable of (i) extracting an audio program
signature from a program signal, (ii) extracting a video

program signature from the program signal, (iii) extracting an audio ancillary code from the program signal, and (iv) extracting a video ancillary code from the program signal.

Any one or more of these detection functions may be used in order to identify the local source of the signals displayed by the television receiver 22'. For example, the tuner of the television receiver 22' may be identified as the source of the signals being displayed by the television receiver 22' if a reference audio signature extracted from an audio output of the television receiver 22' matches a source audio signature extracted from an audio output of the source scanning tuner 66 or if a reference video signature extracted from a video output of the television receiver 22' matches a source video signature extracted from a video output of the source scanning tuner 66.

Similarly, the VCR 28 may be identified as the local source of the signals being displayed by the television receiver 22' if a reference audio signature extracted from an audio output of the television receiver 22' matches a source audio signature extracted from an audio output of the VCR 28 or if a reference video signature extracted from a video output of the television receiver 22' matches a

source video signature extracted from a video output of the VCR 28, the game 26 may be identified as the local source of the signals being displayed by the television receiver 22' if a reference audio signature extracted from an audio output of the television receiver 22' matches a source audio signature extracted from an audio output of the game 26 or if a reference video signature extracted from a video output of the television receiver 22' matches a source video signature extracted from a video output of the game 26, and so on.

The channel selection apparatus 52 may receive a plurality of RF program signals in addition to the RF program signals received by the signal input 46. For example, these other program signals may include off-air channels received by an antenna other than the antenna 46, channels received by way of a CATV cable (which may be received directly, or which may be received through a cable converter), channels received by a satellite dish, and/or the like. The program signals received by the signal input 46 and the other program signals described above are connected through RF multiplexers 80 to the input of the source scanning tuner 66 under control of the controller 68.

The video output 72 from the source scanning tuner 66 is applied to both a source video multiplexer 82 and a reference video multiplexer 84, while the audio output 74 and the second audio program (SAP) output 95 from the source scanning tuner 66 are applied to both a source audio multiplexer 86 and a reference audio multiplexer 88. Also applied to both the source video multiplexer 82 and the reference video multiplexer 84 are (i) the VCR video output 58 from the VCR 28, (ii) a video output 90 from the video game 26, (iii) a VCR video output 92 from a second VCR 94 which might also be used with the television receiver 22', (iv) a video output 96 from a Direct Broadcast Satellite receiver 98, and (v) a video output 100 from the television receiver 22'. Similarly, applied to both the source audio multiplexer 86 and the reference audio multiplexer 88 are (i) the VCR audio output 56 from the VCR 28, (ii) an audio output 102 from the video game 26, (iii) a VCR audio output 104 from the second VCR 94, (iv) an audio output 106 from the Direct Broadcast Satellite receiver 98, and (v) an audio output 108 from the television receiver 22'. The source video multiplexer 82, the reference video multiplexer 84, the source audio multiplexer 86, and the reference audio

5 multiplexer 88 comprise an input multiplexer module 110.
Additionally, the video signal pickup 62 is applied to the
source video multiplexer 82 and to the reference video
multiplexer 84, and the audio signal pickup 64 is applied to
the source audio multiplexer 86 and to the reference audio
multiplexer 88.

10 The output from the source video multiplexer 82 is
connected through a video signal conditioner circuit 111 and
a multiplexer 112 to one input of a digitizer 114' and then
to the signature extraction portion 70' of the digital
signal processor 70. Similarly, the output from the refer-
ence video multiplexer 84 is connected through a video
signal conditioner circuit 113 and a multiplexer 118 to one
input of the digitizer 114' and then to the signature ex-
traction portion 70' of the digital signal processor 70.
15 The signature extraction portion 70', similarly to the
signature extractor 36 of Figure 2, extracts video program
signatures from signals on selected ones of the inputs of
the source video multiplexer 82 and the reference video
multiplexer 84. Accordingly, the signature correlation
20 portion 70'' may correlates reference video signatures
extracted from a video output of the television receiver 22'

to source video signatures extracted from a video output of the game 26, a video output of the VCR 28, a video output of the source scanning tuner 66, a video output of the second VCR 94, and/or a video output of the Direct Broadcast Satellite receiver 98, in order to determine whether the tuner of the television receiver 22', the game 26, the VCR 28, the second VCR 94, or the Direct Broadcast Satellite receiver 98 is the source of the signals being displayed by the television receiver 22'.

The output from the source video multiplexer 82 is also connected directly through the multiplexer 112 and the digitizer 114' to a code reader 114''. Similarly, the output from the reference video multiplexer 84 is also connected directly through the multiplexer 118 and the digitizer 114' to the code reader 114''. The code reader 114'' may be similar to the code reader 34 of Figure 2. The code reader 114'' extracts an ancillary code from a signal on a selected one of the inputs of the source video multiplexer 82 and/or on a selected one of the inputs of the reference video multiplexer 84.

The output from the source audio multiplexer 86 is connected through the multiplexer 112 to one input of the

digitizer 114' and then to the signature extraction portion 70' of the digital signal processor 70. Similarly, the output from the reference audio multiplexer 88 is connected through the multiplexer 118 to one input of the digitizer 114' and then to the signature extraction portion 70' of the digital signal processor 70. The signature extraction portion 70' extracts audio program signatures from signals on selected ones of the inputs of the source audio multiplexer 86 and the reference audio multiplexer 88. Accordingly, the signature correlation portion 70'' may correlate reference audio signatures extracted from an audio output of the television receiver 22' to source audio signatures extracted from an audio output of the game 26, an audio output of the VCR 28, an audio output of the source scanning tuner 66, an audio output of the second VCR 94, and/or an audio output of the Direct Broadcast Satellite receiver 98, in order to determine whether the tuner of the television receiver 22', the game 26, the VCR 28, the second VCR 94, or the Direct Broadcast Satellite receiver 98 is the source of the signals being displayed by the television receiver 22'.

The output from the source audio multiplexer 86 is also connected directly through the multiplexer 112 and the

digitizer 114' to the code reader 114''. Similarly, the output from the reference audio multiplexer 88 is also connected directly through the multiplexer 118 and the digitizer 114' to the code reader 114''. The code reader 114'' extracts an ancillary code from a signal on a selected one of the inputs of the source audio multiplexer 86 and/or on a selected one of the inputs of the reference audio multiplexer 88.

The output from the reference video multiplexer 84 is also connected to a sync matching circuit 116 which compares the standard sync signal as sensed by the sync signal pickup 60 with the sync signals derived from the signal on a selected one of the inputs of the reference video multiplexer 84. The sync matching circuit 116 passes a match between the standard sync signal as sensed by the sync signal pickup 60 and a sync signal derived from the signal on a selected one of the inputs of the reference video multiplexer 84 to the digital signal processing module 71.

With this arrangement, a reference video signature extracted from a video output of the television receiver 22' may be compared to source video signatures extracted from a

video output of the game 26, a video output of the VCR 28, a
video output of the source scanning tuner 66, a video output
of the second VCR 94, a video output of the Direct Broadcast
Satellite receiver 98, and the like in order to determine
5 the local source of the signals displayed by the television
receiver 22'. Alternatively or in addition, a reference
audio signature extracted from an audio output of the tele-
vision receiver 22' may be compared to source audio signa-
tures extracted from an audio output of the game 26, an
10 audio output of the VCR 28, an audio output of the source
scanning tuner 66, an audio output of the second VCR 94, an
audio output of the Direct Broadcast Satellite receiver 98,
and the like in order to determine the local source of the
signals displayed by the television receiver 22'.

15 Because the correlation of signatures is computa-
tionally expensive, the digital signal processing module 71
may first control the reference video multiplexer 84 in
order to pass the video signal on the video output 72 of the
source scanning tuner 66 to the sync matching circuit 116
20 which matches suitable synchronization components of the
video output of the source scanning tuner 66 and from the
sync signal pickup 60. Until a match is found, the control-

ler 68 causes the source scanning tuner 66 to sequentially tune to the possible signal sources.

When a match between synchronization components is found, the digital signal processing module 71 controls the source video multiplexer 82 in order to pass the video signal currently on the video output 72 of the source scanning tuner 66 to the video signal conditioner circuit 111, the multiplexer 112, and the signature extraction portion 70', and the digital signal processing module 71 controls the reference video multiplexer 84 in order to pass the video signal on the video output 100 (or 67) of the television receiver 22' to the video signal conditioner circuit 113, the multiplexer 118, and the signature extraction portion 70'. (The video signal conditioner circuit 113 is always bypassed when using the video signal from the video signal pickup 62.) The signature extraction portion 70' and the signature correlating portion 70'' of the digital signal processor 70 extracts and correlates video signatures from the video signal corresponding to the channel selected by the source scanning tuner 66 and the video signal corresponding to a channel selected by the television receiver 22'. These channels are the channels that are in sync as

determined by the sync matching circuit 116. If a match is not found, it may be concluded that the sync tested by the sync matching circuit 116 relates to different channels. Accordingly, the controller 68 steps the source scanning tuner 66 to the next channel to restart the process of finding synchronization and, if synchronization is found, of extracting and comparing video signatures. If a match of video signatures is found, the tuner of the television receiver 22' is identified as the local source of the signals displayed by the television receiver 22'.

Alternatively, when a match between synchronization components is found, the digital signal processing module 71 controls the source audio multiplexer 86 in order to pass the audio signal on the audio output 74 of the source scanning tuner 66 to the multiplexer 112 and the signature extraction portion 70', and the digital signal processing module 71 may control the reference audio multiplexer 88 in order to pass the audio signal on the audio output 108 (or the audio signal pickup 64) of the television receiver 22' to the multiplexer 118 and the signature extraction portion 70'. The signature extraction portion 70' and the signature correlating portion 70'' of the digital

signal processor 70 extracts and correlates audio signatures from the audio signal corresponding to the channel selected by the source scanning tuner 66 and the audio signal corresponding to a channel selected by the television receiver 22'. These channels are the channels that are in sync as determined by the sync matching circuit 116. If a match is not found, it may be concluded that the sync found by the sync matching circuit 116 relates to different channels. Accordingly, the controller 68 steps the source scanning tuner 66 to the next channel to restart the process of finding synchronization and, if synchronization is found, of extracting and comparing audio signatures. If a match of audio signatures is found, the tuner of the television receiver 22' is identified as the local source of the signals displayed by the television receiver 22'.

After a match is thus found, the identity of this signal source may be confirmed by reading an ancillary code, if present, from the video signal on the video output 72 of the source scanning tuner 66. It should be noted here that, if the video signal pickup 62 is used to derive a video signal from the television receiver 22', and if ancillary codes are inserted in the vertical blanking interval of

video signals, the ancillary code cannot be read from the video signal on the video signal pickup 62 because, in many modern television sets, the vertical blanking interval is not present in video signal at the point where the video signal pickup 62 picks up the video signal. Accordingly, ancillary codes can instead be read from the video output 72 of the source scanning tuner 66 when the source scanning tuner 66 is tuned to the channel to which the television receiver 22' is tuned. However, if the video output 100 is used to derive a video signal from the television receiver 22', if the video output 100 is at baseband, and if ancillary codes are inserted in the vertical blanking interval of video signals, the ancillary code can be read from the video signal on the video output 100 because the vertical blanking interval is present in the baseband video signal. Alternatively, the identity of this signal source may be confirmed by reading an ancillary code, if present, from the audio signal on the audio output 74 of the source scanning tuner 66 or on the audio output 108 (or 64) of the television receiver 22'.

If signatures extracted from all of the channels to which the source scanning tuner 66 may be tuned do not

match signatures extracted from the output of the television receiver 22', reference video and/or audio signatures extracted from a video and/or audio output of the television receiver 22' may be compared to source video and/or audio signatures extracted from a video and/or audio output of the game 26, from a video and/or an audio output of the VCR 28, from a video and/or an audio output of the second VCR 94, from a video and/or an audio output of the Direct Broadcast Satellite receiver 98, and the like in a similar manner in order to determine whether any of these local sources is the local source of the signals displayed by the television receiver 22'.

Also, various modes of the VCR 28 (and of the second VCR 94) can be determined by the arrangement of the present invention. Figure 4 discloses in table form the operation of the present invention in order to monitor the modes of a VCR. As shown in Figure 4, if the erase head of the VCR 28 is active, if the outputs of the VCR 28 and of the source scanning tuner 66 match, and if the outputs of the VCR 28 and of the television receiver 22' match, then it may be concluded that the VCR 28 is in the RECORD mode and

that the program being recorded is also being viewed at the same time.

5 The operation of the erase head of the VCR 28 can be detected by the digital signal processing module 71 from a VCR erase detector 119 which is associated with the VCR 28. (Also, a VCR erase detector 120 may be associated with the second VCR 94.) The erase head detector 119 may be of the sort disclosed by Vitt et al. Alternatively, the code reader 114 may be arranged to detect an artifact of the
10 erase signal of the VCR 28 from the VCR audio output 56 of the VCR 28 by use of either the source audio multiplexer 86 or the reference audio multiplexer 88.

5 In order to determine if the outputs of the VCR 28 and of the source scanning tuner 66 match, the video outputs of the VCR 28 and of the source scanning tuner 66 may be correlated. For example, the digital signal processing module 71 may control the source video multiplexer 82 in order to pass the video signal on the video output 72 to the video signal conditioner circuit 111, the multiplexer 112,
0 and the signature extraction portion 70', and the digital signal processing module 71 may control the reference video multiplexer 84 in order to pass the video signal on the VCR

video output 58 to the video signal conditioner circuit 113,
the multiplexer 118, and the signature extraction portion
70'. The signature extraction portion 70' and the signature
correlating portion 70'' of the digital signal processor 70
5 extracts and correlates video signatures from a video signal
corresponding to a channel selected by the source scanning
tuner 66 and from a video signal corresponding to a channel
selected by the VCR 28. If these video signatures do not
match, the controller 68 may step the source scanning tuner
10 66 through each of the channels until a match is found.

Alternatively, the digital signal processing
module 71 may control the source audio multiplexer 86 in
order to pass the audio signal on the audio output 74 to the
multiplexer 112 and the signature extraction portion 70',
15 and the digital signal processing module 71 may control the
reference audio multiplexer 88 in order to pass the audio
signal on the VCR audio output 56 to the multiplexer 118 and
the signature extraction portion 70'. The signature extrac-
tion portion 70' and the signature correlating portion 70''
20 of the digital signal processor 70 extracts and correlates
audio signatures from the audio signal corresponding to a
channel selected by the source scanning tuner 66 and from

the audio signal corresponding to a channel selected by the VCR 28. If these audio signatures do not match, the controller 68 may step the source scanning tuner 66 through each of the channels until a match is found.

5 In order to determine if the outputs of the VCR 28 and of the television receiver 22' match, the video outputs of the VCR 28 and of the television receiver 22' may be correlated. The correlation of the outputs of the VCR 28 and of the television receiver 22' also can be determined by
10 the digital signal processing module 71. For example, the digital signal processing module 71 may control the source video multiplexer 82 in order to pass the video signal on the video output 100 from the television receiver 22' to the video signal conditioner circuit 111, the multiplexer 112,
.5 and the signature extraction portion 70', and the digital signal processing module 71 may control the reference video multiplexer 84 in order to pass the video signal on the video output 58 of the VCR 28 to the video signal conditioner circuit 113, the multiplexer 118, and the signature
10 extraction portion 70'. The signature extraction portion 70' and the signature correlating portion 70'' of the digital signal processor 70 extracts and correlates video signa-

tures from the video signal corresponding to a channel selected by the VCR 28 and the video signal corresponding to a channel selected by the television receiver 22'.

Alternatively, the digital signal processing module 71 may control the source audio multiplexer 86 in order to pass the audio signal on the audio output 108 from the television receiver 22' to the multiplexer 112 and the signature extraction portion 70', and the digital signal processing module 71 may control the reference audio multiplexer 88 in order to pass the audio signal on the audio output 56 of the VCR 28 to the multiplexer 118 and the signature extraction portion 70'. The signature extraction portion 70' and the signature correlating portion 70'' of the digital signal processor 70 extracts and correlates audio signatures from the audio signal corresponding to a channel selected by the VCR 28 and the audio signal corresponding to a channel selected by the television receiver 22'.

If the television receiver 22' does not have output jacks so that the video output 100 and the audio output 108 are not present and so that the video signal pickup 62 and the audio signal pickup 64 are instead used to

sense the video and audio signals of the television receiver 22', signatures from the video signals on the video output 58 of the VCR 28 and on the video signal pickup 62 of the television receiver 22' may be correlated in the manner described above, or signatures from the audio signals on the audio output 56 of the VCR 28 and on the audio signal pickup 64 of the television receiver 22' may be correlated in the manner described above.

As also shown in Figure 4, if the erase head of the VCR 28 is active, if the outputs of the VCR 28 and of the source scanning tuner 66 match, and if the outputs of the VCR 28 and of the television receiver 22' do not match, then it may be concluded that the VCR 28 is in the RECORD mode, but that the program being recorded is not also being viewed on the television receiver 22' at the same time. The operation of the erase head of the VCR 28 can be detected as described above, the outputs of the VCR 28 and of the source scanning tuner 66 can be correlated as described above in order to determine that they match, and the outputs of the VCR 28 and of the television receiver 22' can be correlated as described above in order to determine that they do not match.

As shown in Figure 4, if the erase head of the VCR 28 is not active, if the outputs of the VCR 28 and of the source scanning tuner 66 do not match, and if the outputs of the VCR 28 and of the television receiver 22' do match, then it may be concluded that the VCR 28 is in the PLAY mode.

The operation of the erase head of the VCR 28 can be detected as described above, the outputs of the VCR 28 and of the source scanning tuner 66 can be correlated as described above in order to determine that they do not match, and the outputs of the VCR 28 and of the television receiver 22' can be correlated as described above in order to determine that they do match.

Again as shown in Figure 4, if the erase head of the VCR 28 is not active, if the outputs of the VCR 28 and of the source scanning tuner 66 match, and if the outputs of the VCR 28 and of the television receiver 22' match, then it may be concluded that the VCR 28 is not recording or playing, but is instead being used to tune the television receiver 22', to fast forward a cassette (or tape), or to rewind a cassette (or tape). The use of the VCR 28 as a tuner may be credited by the program signal source detector 44. The operation of the erase head of the VCR 28 can be

detected as described above, the outputs of the VCR 28 and of the source scanning tuner 66 can be correlated as described above in order to determine that they match, and the outputs of the VCR 28 and of the television receiver 22' can be correlated as described above in order to determine that they match.

As finally shown in Figure 4, if the erase head of the VCR 28 is not active, if the outputs of the VCR 28 and of the source scanning tuner 66 do not match, and if the outputs of the VCR 28 and of the television receiver 22' also do not match, then it may be concluded that the VCR 28 is off. The operation of the erase head of the VCR 28 can be detected as described above, the outputs of the VCR 28 and of the source scanning tuner 66 can be correlated as described above in order to determine that they do not match, and the outputs of the VCR 28 and of the television receiver 22' can be correlated as described above in order to determine that they do not match. The digital signal processing module 71 may determine the on or off state of the television receiver 22' by detecting the presence or loss of a sync signal on the sync signal pickup 60.

Also, the arrangement of Figure 3 may be used to identify programs being played by the VCR 28 or being displayed by the television receiver 22'. For example, video and/or audio program identifying ancillary codes contained in the program signal being recorded by the VCR 28 may be read by the code correlating portion 114'' and may be stored in a memory of the digital signal processing module 71. The stored video and/or audio program identifying ancillary codes can be compared with those read by the code correlating portion 114'' during the subsequent PLAY mode of the VCR 28 in order to determine if and when the recorded program signal is played back. The video and/or audio program identifying ancillary codes read by the code correlating portion 114'' during either the RECORD mode or the subsequent PLAY mode of the VCR 28 may also be used to identify the programs being played in accordance with the teachings of the aforementioned U.S. Patent No. 5,481,294.

If video and/or audio program identifying ancillary codes are not present in the signals being recorded and/or played, characteristic video and/or audio program signatures of the program signal being recorded by the VCR 28 may be extracted by the signature extraction portion 70'

and may be stored in the memory of the digital signal processing module 71. The stored characteristic video and/or audio signatures can be compared by the signature correlating portion 70'' with those extracted by the signature extraction portion 70' during a subsequent PLAY mode in order to determine if and when the recorded program signal is played back. If a match is found, the signatures extracted during play or recording may be compared to known signatures previously extracted from known programs by the local metering site 16 or by the source scanning tuner 66 in order to identify the recorded and/or played program in accordance with the teachings of the aforementioned U.S. Patent No. 5,481,294.

Similarly, video and/or audio program identifying ancillary codes of a program signal tuned by the tuner of the television receiver 22' may be read by the code correlating portion 114'' at the video and/or audio outputs of the television receiver 22'. The video and/or audio program identifying ancillary codes may be used to identify the programs displayed by the television receiver 22' in accordance with the teachings of the aforementioned U.S. Patent No. 5,481,294. If video and/or audio program identifying ancil-

lary codes are not present in the signals at the output of the television receiver 22', characteristic video and/or audio program signatures of the program signal at the output of the television receiver 22' may be extracted by the signature extraction portion 70'. These signatures may be compared to known signatures previously extracted from known programs by the local metering site 16 or by the source scanning tuner 66 in order to identify the displayed program in accordance with the teachings of the aforementioned U.S. Patent No. 5,481,294.

Programs being recorded and/or played by the second VCR 94, games from the video game 26 being displayed by the television receiver 22', and programs from the Direct Broadcast Satellite receiver 98 being displayed by the television receiver 22', may be similarly identified through the use of program identifying ancillary codes and characteristic program signatures. It should be noted, however, that the playing of rented or purchased cassettes (or tapes) is often more common than playing back time-shifted, previously recorded programs. Accordingly, it is expected that most attempts to use characteristic program signatures in order to identify programs being played on the VCR 28 will

fail to yield an identifying match. However, program identifying ancillary codes are frequently added to pre-recorded cassettes (or tapes) so that, in those cases, the program signal source detector 44 installed in the statistically selected household 14 will still be able to identify the program being played by the VCR 28.

Certain modifications of the present invention have been discussed above. Other modifications will occur to those practicing in the art of the present invention. For example, although the present invention has been specifically described in connection with a television audience measurement system, the present invention may be used in connection with other systems such as program verification systems.

Also, although the present invention has been described in connection with the monitoring of television receivers, the present invention may be used in connection with the monitoring of other receivers, such as radio receivers.

Similarly, although the present invention has been described in connection with monitoring VCRs, the present invention may be used in connection with monitoring other

recording and/or playing equipment such as disk players, audio cassette and disk recorders/players, and the like, and in connection with signal sources that are less complex than VCRs and like equipment.

5 Moreover, as described above, the signature correlating portion 70'' of the digital signal processor 70 and the code correlating portion 114'' of the code reader 114 are located in the statistically selected household 14. However, the signature correlating portion 70'' and the code correlating portion 114'' instead may be located in the
10 central site 18.

 Furthermore, as described above, signatures are extracted from an output of the television receiver 22' and from an output of a local source of program signals, and
15 these signatures are correlated in order to identify the source as the source of the signals being displayed by the television receiver 22'. These signatures may be exact analog or digital representations of the relevant programs signals so that the output of the television receiver 22'
20 and the output of a source to be identified as the source of the program signals being displayed by the television receiver 22' may be directly correlated either in analog form

or in digital form without the necessity of sampling the program signals. Alternatively, the signatures may be sampled representations of the relevant programs signals.

Accordingly, the description of the present invention is to be construed as illustrative only and is for the purpose of teaching those skilled in the art the best mode of carrying out the invention. The details may be varied substantially without departing from the spirit of the invention, and the exclusive use of all modifications which are within the scope of the appended claims is reserved.
